I. Introducing

Welcome on the complete Ultimate Mailer Getting Started Guide. This book is written in a progressive way just like the software, it means that to reach your ends you must read carefully all the chapters of this book. First of all you need .NET Framework 4.5.2 installed on your computer to run Ultimate Mailer.

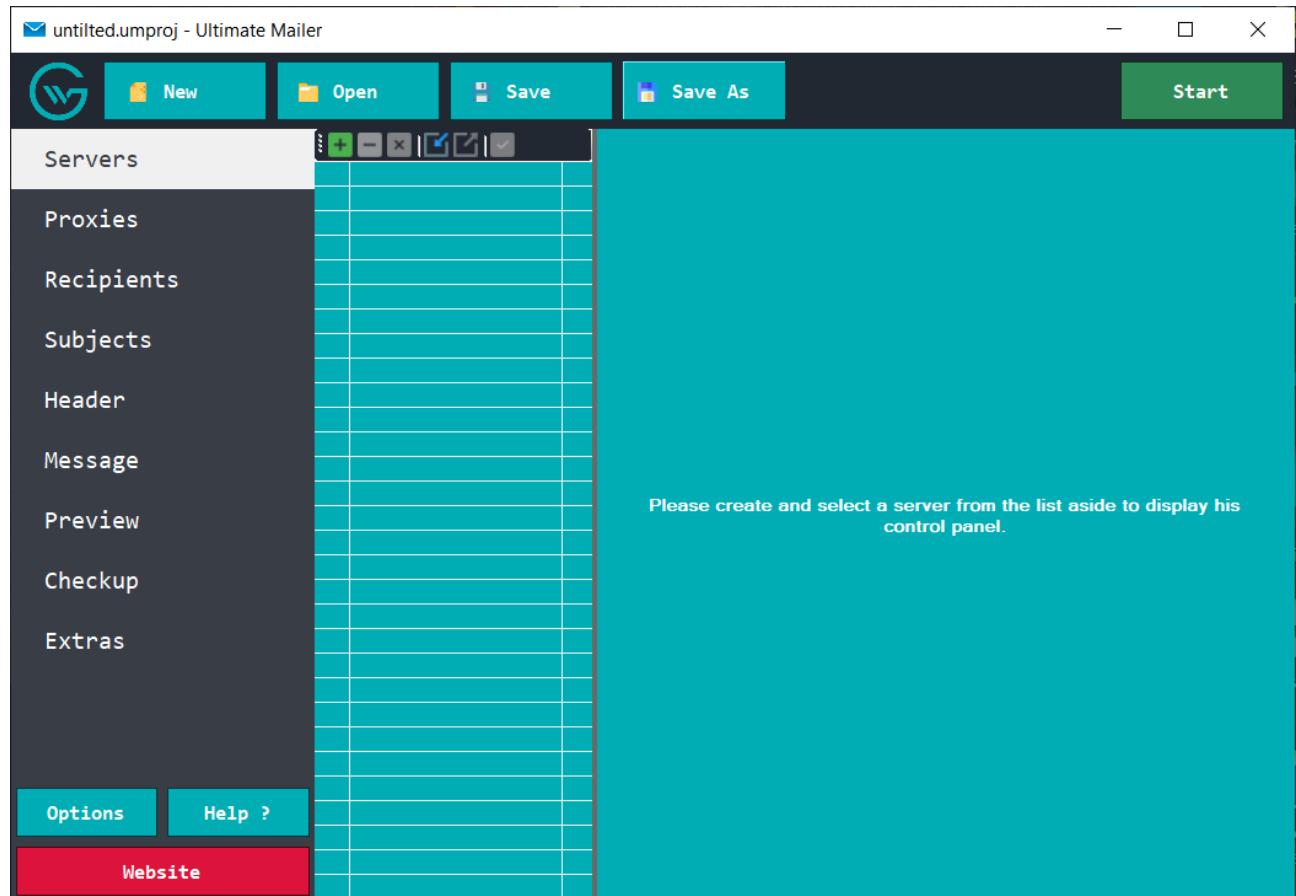

If you look closely the main UI of Ultimate Mailer you will notice that the tabs on the left are in fact the different steps to follow to configure your email campaigns. From the top to the bottom, the servers tab is the first step and the extras tab and the start button are the lastest.

II. Servers

The Servers tab is the default tab open when launching the software. This tab allows you to configure multiples SMTP servers to ensure send of your messages, continue reading this chapter to find out how.

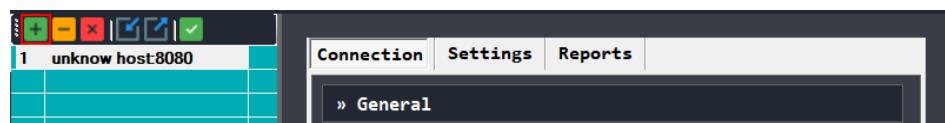

You must start by adding a new server by clicking the + button in the toolbar and select it in the list below the toolbar to display his control panel. You can now start to configure your SMTP server by the way you want to use it.

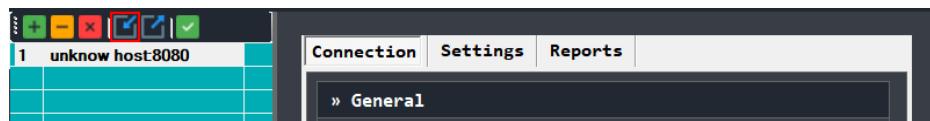

1. Management

There is many way to add or import servers, the first one is to simply click the “+” button in the toolbar to create a new server then select it inside the list above to display his control panel.

You can import a large amount of SMTP servers in one time. Ultimate Mailer support servers import with multiple file formats, such as TXT or CSV.

The import function is accessible through the “” button then choose the file where the servers are stored in the open file dialog.

For TXT file format, the import pattern is as follows :

host:port:username:password:email:name

mail.google.com:465:user1@dom.fr:password:user1@dom.fr:John Doe

mail.google.com:465:user2@dom.fr:password:user2@dom.fr:John Doe

For CSV file format, the import pattern is as follows :

host,port,username,password,email,name

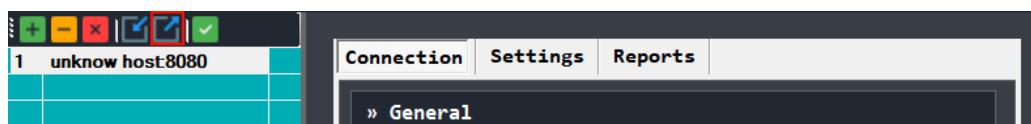

mail.google.com,465,user1@gmail.com,password,user1@gmail.com,John Doe

mail.google.com,465,user2@gmail.com,password,user2@gmail.com,John Doe

#1 Bulk email sending software.

You can also export your SMTP servers list into a file after it have been checked or just to save or use it in another software. Ultimate Mailer support servers export with multiple file formats, such as TXT or CSV.

To export, click the button “✗” and choose the file name and type in the save file dialog.
Later you can import this servers list into another Ultimate Mailer project.

1. Connection

a. General

SMTP for Simple Mail Transfer Protocol is an outgoing email server. To access it you need the "Host" address of the server which can be an IP address or a domain name, and a "Port". The most commonly use are the following 25, 465, 587.

You also need to define which security "Protocol" will be used to connect, since SSL protocol is deprecated most of the servers uses TLS 1.2 protocol. You can find this information on your SMTP provider's website or by asking your vendor.

**b. Authentication**

SMTP servers are mostly protected by an authentication system, if this is not your case click on the checkbox at top right to disable authentication :

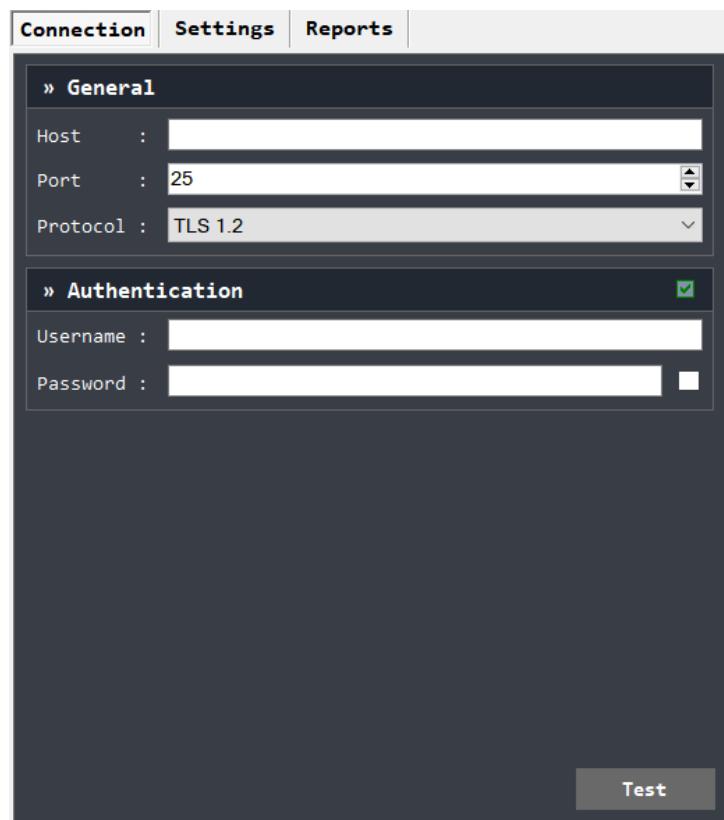

In this panel you must enter your login credentials for your SMTP server, the "Username" in most cases corresponds to your email address and your "Password" for example with a google account use the same credentials as to login on gmail.

Public SMTP servers like Gmail or Yahoo often need authorization to accept external connection from less secure app. You can change this inside your SMTP account provider settings.

c. Test

Once all connection informations are set up you can try to reach SMTP server to make sure everything works properly before continue. To do this click on the "Test" button at the bottom of the connection tab :

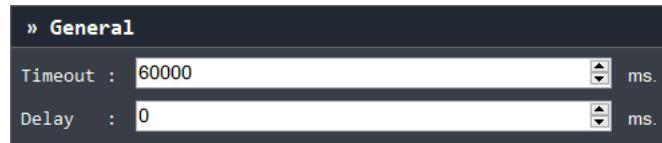

This verifies the connection and authentication to the SMTP server. If you receive an error message, simply follow the on-screen instructions. If you encounter an SSL certificate error, please read the FAQ section dedicated to this issue at the end of this ebook.

2. Settings

a. General

"Timeout" field is used to define the period in milliseconds after which it is considered that the connection or authentication on the SMTP server or the email sending has failed.

A timeout too low will generate timeout errors when connecting on SMTP server or sending messages with it, if you have a poor internet connection so keep it with its default value of 60000ms if it's your case.

The "Delay" field is used to define the period to wait in milliseconds between each message. You can also use it if your SMTP have a send limit per minute . For example your SMTP server do not allow more than 30 messages per minutes like Office 365, so you define a delay of 2000 ms.

**b. Sender**

This panel allow you to set-up sender “Name” and sender “Email” address. Sender “Name” is not a required field but the sender “Email” must be filled. You must fill sender “Email” field with the email address configured with your SMTP server, to add SPF, DKIM and DMARC sender identification security into the mail header. This process is completely handled by the SMTP server.

A screenshot of a software interface titled "» Sender". It contains two input fields: "Name :" followed by a dropdown menu, and "Email :" followed by a text input field.

You also must ensure that your SMTP server is configured to sign the sender email address. If you use a public SMTP servers such as Google or Yahoo emails address are already signed by the server without any configuration, for private SMTP servers please inquire at your vendor.

c. Limit

Here you have to set the sending limits of your SMTP server, the program will count the number of messages sent successfully during all campaigns, once the limit reached it will automatically rotate the SMTP server used to send the messages. If no other server is available, the program will simply wait for one.

| Interval | Limit (msg.) |
|----------|--------------|
| Session | 100 |
| Hourly | 100 |
| Daily | 500 |
| Monthly | 2000 |

"Session" field is used to bypass sending limit per connection, the SMTP server will be automatically disconnected when the limit is reached and reconnected once session delay have been pass to continue sending.

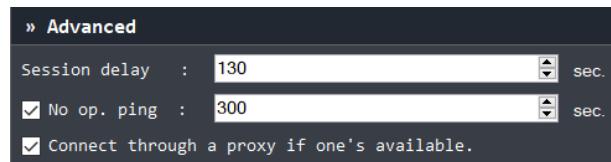

If your SMTP server have an hourly sending limit, check "Hourly" field and type the amount of message that can be sent in an interval of one hour. If the limit is reached the SMTP server will not be available for an hour.

If your SMTP server have a daily sending limit, check "Daily" field and type the amount of message that can be sent in in an interval of one day. If the limit is reached the SMTP server will not be available for a day.

If your SMTP server have a monthly sending limit, check "Monthly" field and type the amount of message that can be sent in in an interval of one month. If the limit is reached the SMTP server will not be available for a month.

d. Advanced

Sometimes public SMTP server need a delay between each session to reset the sending limit per session otherwise the connection will be denied or session will stay the same. To correct this you have to define the right "Session delay". For example Google accounts need 130 seconds delay between each session to allow a reconnection or reset sending limit by session.

The "No op. ping" feature maintains the connection to the SMTP server if no operation is done with it. For exemple SMTP server google automatically closes the connection after 540 seconds of inactivity.

Enable the "No op. ping" feature if you use more than one SMTP server to not lose the connection and save sending time.

3. Reports

The reports system allows you to view the current status of your SMTP server. From first report date to last report date. The report feature works like this, when you send an email with your SMTP server, the software create a stats dataset over the current period, then the dataset expire after one month by default.

| Connection Settings Reports | |
|----------------------------------|-----------------------|
| Available | ✓ |
| Availability | - |
| Performed | 0 message(s). |
| Sent | 0 message(s). |
| Error | 0 message(s). |
| Hourly | 0 message(s). |
| Daily | 0 message(s). |
| Monthly | 0 message(s). |
| Capabilities | Unlimited message(s). |

You can change report “Validity” and “Duration” fields in options window, this allow you to respectively store less data by reducing the “Validity” value or have more precise informations by reducing “Duration” value, so if you reduce this value it will also increase the amount of data stored for all SMTP.

The value of the "Available" field tells you the current status of your SMTP server. If a limit has been reached the server will be unavailable and marked in red into servers lists otherwise is marked in green.

"Availability" field tells you if your server is unavailable the moment it becomes available again.

The field "Capabilities" indicates the number of messages that your SMTP server will be able to send without encounter a limit during the next email campaign, this field don't take in consideration the session limit.

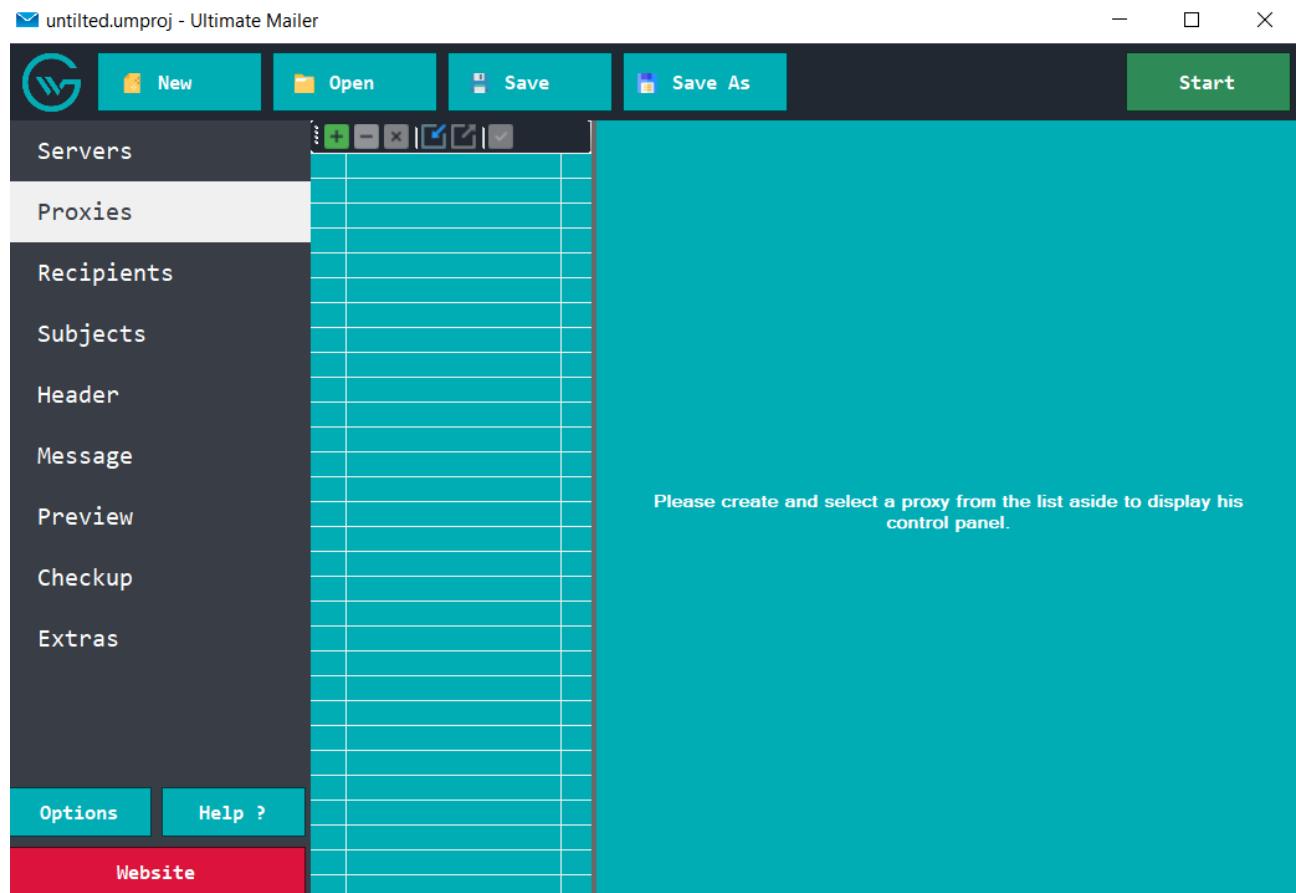

You need to save your project after each campaign if you want to keep track of email sent for each SMTP server once the software is closed.

III. Proxies

Into this tab, you can configure multiple proxies, it's useful if you want to hide your personal computer IP address or simulate email sending from multiple sources.

Please note that using a public proxy can damage your sending reputation as well as your inbox rate, please use trusted private proxies.

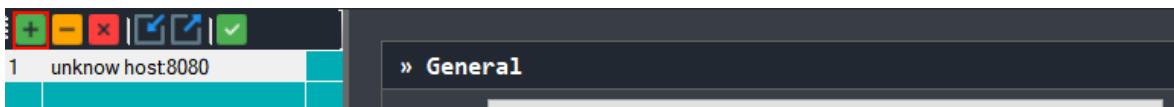

Ultimate Mailer support the use of HTTP, SOCKS4, SOCKS4A and SOCKS5 proxy, you can add a proxy by clicking the + button inside the toolbar and then select it in the list above to display his control panel.

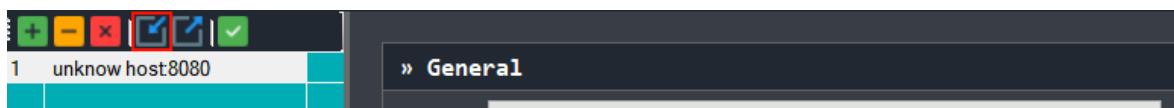

1. Management

There is many way to add or import proxies, the first one is to simply click the “+” button in the toolbar to create a new proxy then select it inside the list above to display his control panel.

You can import a large amount of proxies in one time. Ultimate Mailer support recipients import with multiple file formats, such as TXT or CSV.

The import function is accessible through the “” button then choose the file where the proxies are stored in the open file dialog.

For TXT file format, the import pattern is as follows :

```
type:host:port:username:password  
0:192.0.0.1:8080:username:password  
0:192.0.0.2:8080:username:password
```

For CSV file format, the import pattern is as follows :

```
type,host,port,username,password  
0,192.0.0.1,8080,username,password  
0,192.0.0.2,8080,username,password
```

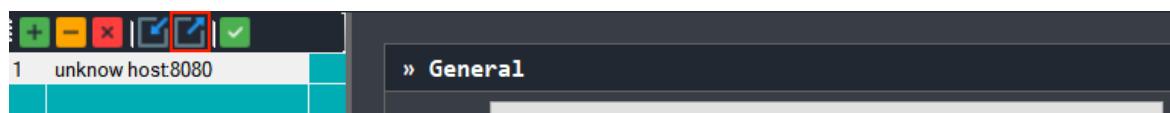

#1 Bulk email sending software.

The 'type' field can have these different values:

| HTTP | SOCKS4 | SOCKS4a | SOCKS5 |
|------|--------|---------|--------|
| 0 | 1 | 2 | 3 |

You can also export your proxies server list into a file after it have been checked or just to save or use it in another software. Ultimate Mailer support proxies export with multiple file formats, such as TXT or CSV.

To export, click the button “U” and choose the file name and type in the save file dialog. Later you can import this proxies list into another Ultimate Mailer project.

2. General

In computer networking, a proxy server is a server application that acts as an intermediary for requests from clients seeking resources from servers that provide those resources.[1] A proxy server thus functions on behalf of the client when requesting service, potentially masking the true origin of the request to the resource server.

To connect on the proxy server you need to define the “Type” of the proxy server you want to use, it can be HTTP, SOCKS4, SOCKS4A and SOCKS5. Then complete the “Host” field, it's either an ip address or a domain name and the “Port” field it's a number between 0 and 65535.

3. Authentication

A screenshot of a software interface titled "» Authentication". It contains two input fields: "Username :" and "Password :". Both fields have a teal background color. To the right of the "Username :" field is a checked checkbox (indicated by a green checkmark). To the right of the "Password :" field is an unchecked checkbox (indicated by a small square).

Most of the time proxy servers do not have a user and password authentication system, they simply allow a range of IP addresses to connect or not to the server.

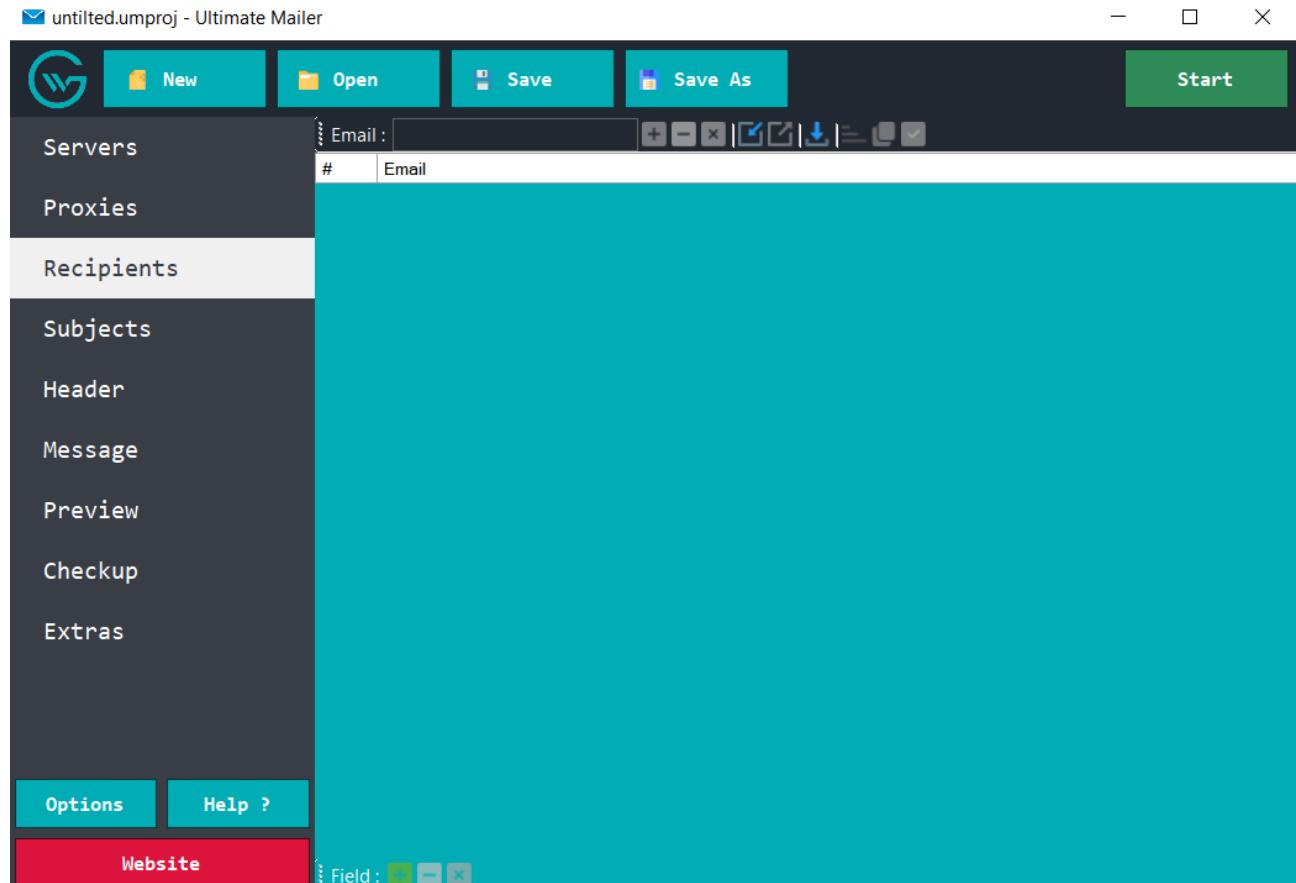

But if yours uses this type of authentication you can activate it by clicking on the checkbox at the top right of the panel.

A screenshot of the same "» Authentication" panel. The checkbox to the right of the "Username :" field is now highlighted with a red border, while the other elements remain the same.

IV. Recipients

This tab is also one of the most important, it allow you to add / import and export recipients, but also data about them like the name, address or whatever you want.

The recipient field feature is one of the major upgrade between Ultimate Mailer V2 and V3, you can discover how it works by reading this chapter.

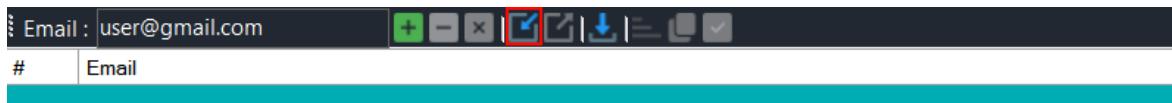

1. Management

There is many way to add or import recipients, the first one is to input the email address you want to add in your list inside the “Email” field in the toolbar, then simply click the “+” button to add it to the list.

If you want to import a large amount of recipients in one time, this is also possible. Ultimate Mailer supports recipients import with multiple file formats, such as TXT or CSV.

The import function is accessible through the “↙” button then choose the file where the recipients are stored in the open file dialog.

For TXT file format, the import pattern is as follows :

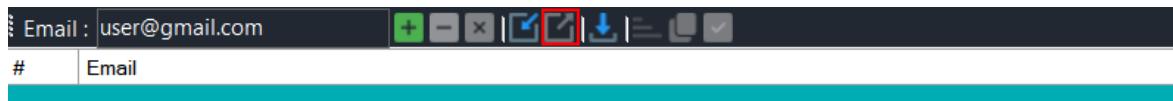

```
user1@domain.com:field1:field2:field3:field4:[etc]  
user2@domain.com:field1:field2:field3:field4:[etc]
```

For CSV file format, the import pattern is as follows :

```
user1@domain.com,field1,field2,field3,field4,[etc]  
user2@domain.com,field1,field2,field3,field4,[etc]
```

You can also export your recipients list into a file after it have been checked or just to save or use it in another software. Ultimate Mailer support recipients export with multiple file formats, such as TXT or CSV.

To export, click the button “” and choose the file name and type in the save file dialog. Later you can import this recipient list into another Ultimate Mailer project.

2. Fields

Here you can create recipient fields, this is useful if you want to store a name, address, phone number or something else with each recipient. You can then use them in your email to make them more targeted and thus increase your inbox rate. To create a new field for all recipients please click the “+” button.

Then, you can import fields with the recipient by following the method described above or directly insert data into a field by double-tapping the cell in question next to the recipient.

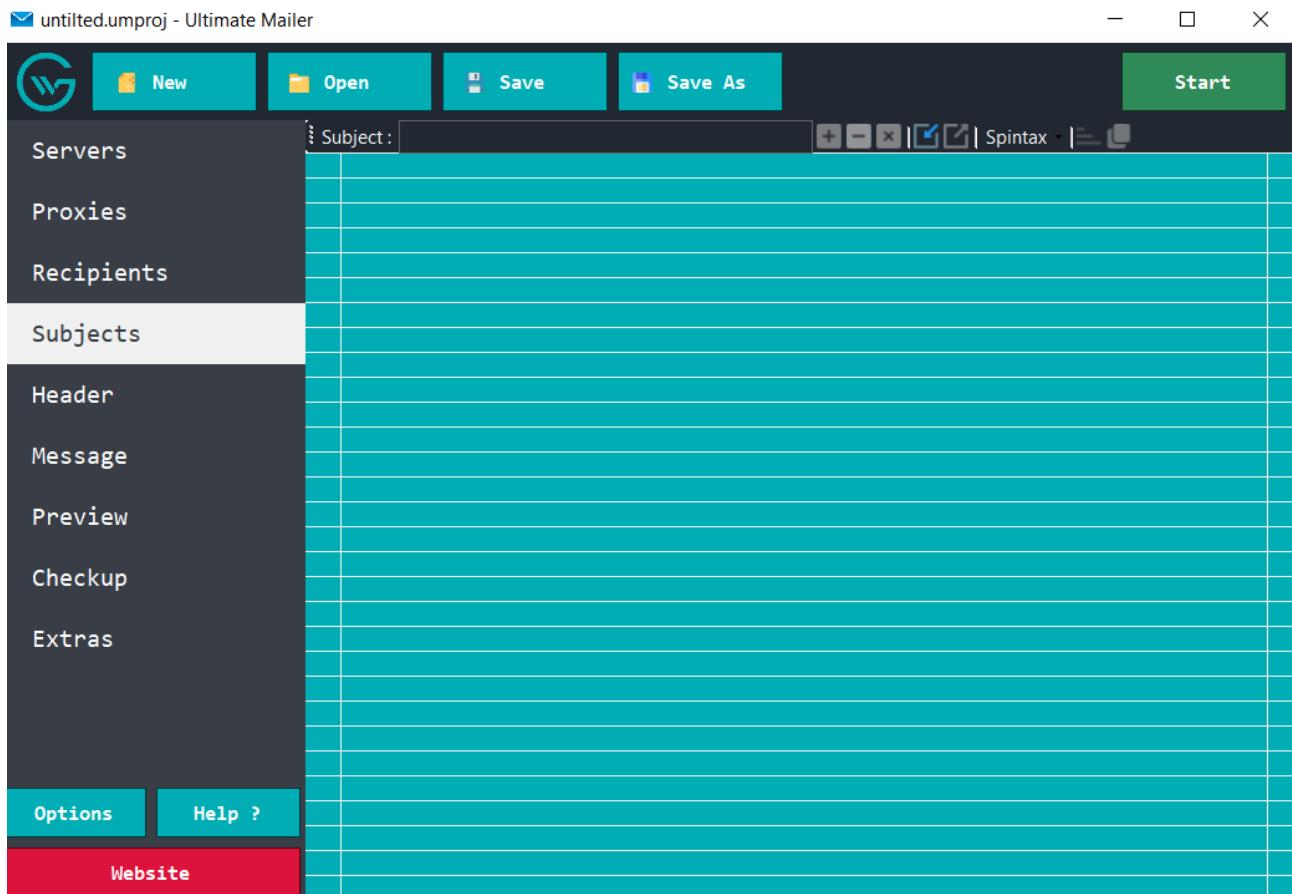

| # | Email | Field n°1 | Field n°2 | Field n°3 |
|---|----------------|-----------|-----------|-----------|
| 1 | user@gmail.com | Field 1 | | |

The recipient field variable works like that, just type **{TO_FIELD, num}** where you want to display the field and replace 'num' by the actual index of the recipient field you want to display from 1 to 4 in the exemple.

V. Subjects

Add as many subjects as needed in this tab. The more subjects your email campaign has, the more results you can expect ! Create, import and export subjects from this tab, also insert Ultimate Mailer variables, also named spintax to maximize randomization.

1. Management

There is many way to add or import subjects, the first one is to fill the “Subject” field and simply click the “+” button in the toolbar to add a subject in the list.

You can also import a large amount of subjects in one time. Ultimate Mailer support subjects import with multiple file formats, such as TXT or CSV.

The import function is accessible through the “I” button then choose the file where the servers are stored in the open file dialog.

For TXT file format, the import pattern is as follows :

```
subject
Hello world !
Hello world ! How are you ?
```

For CSV file format, the import pattern is as follows :

```
subject
Hello world !
Hello world ! How are you ?
```

You can also export your subjects list into a file to save or use it in another software.

#1 Bulk email sending software.

Ultimate Mailer support subjects export with multiple file formats, such as TXT or CSV.

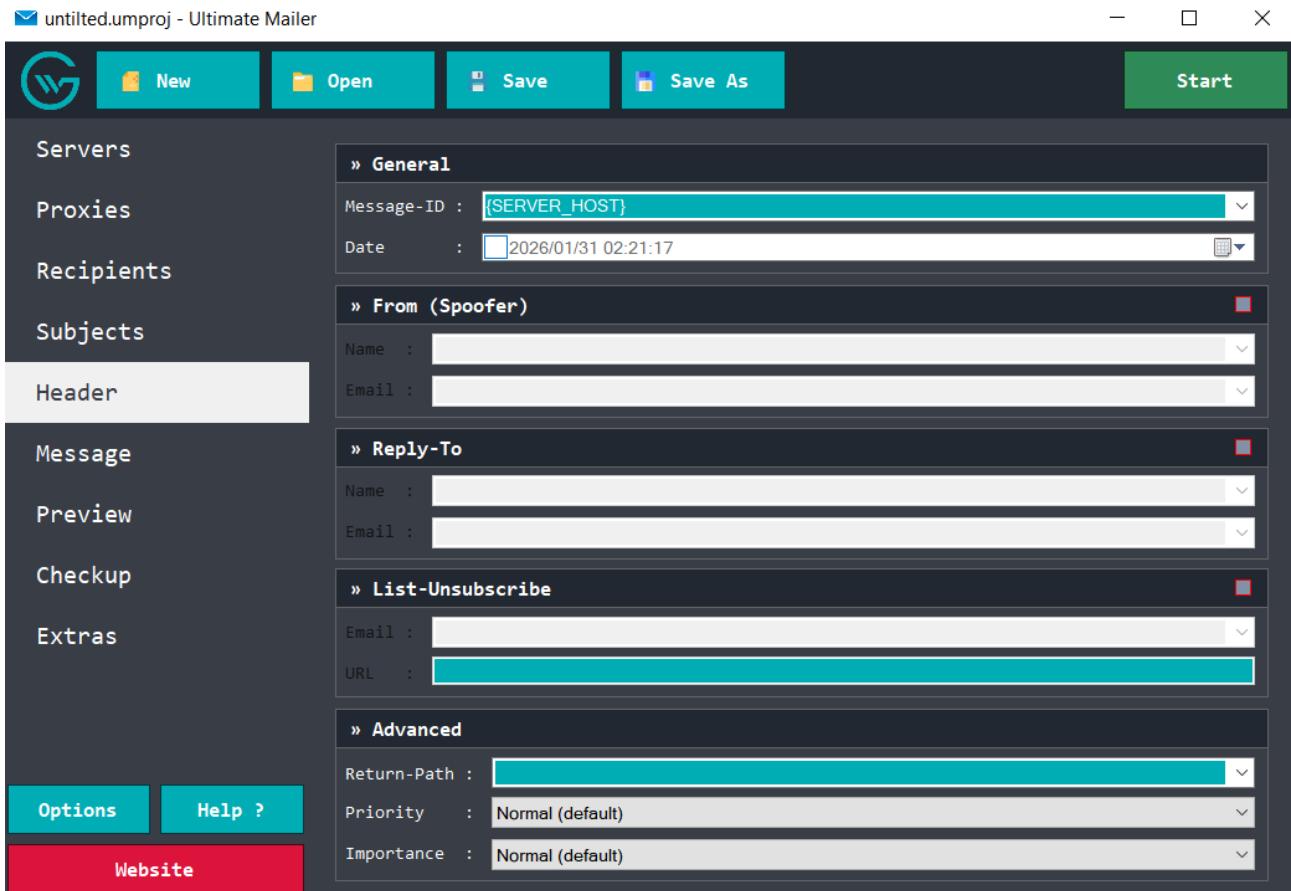

To export, click the button “” and choose the file name and type in the save file dialog.
Later you can import this subjects list into another Ultimate Mailer project.

VI. Header

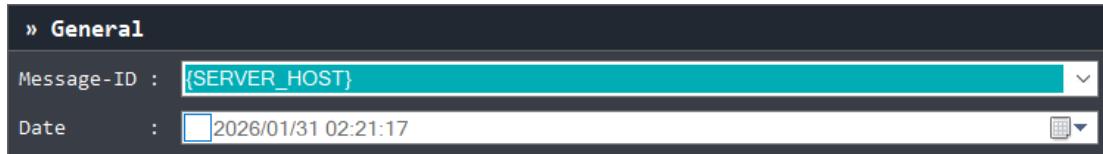

This tab allows you to define or modify certain information in the header of your emails. read this chapter carefully to obtain the best possible results on your next mailing campaign.

The email header is a log of technical information visible to both sender and receiver, although less easily accessible than the body of the message. It contains details about the sender, recipient and message: the email addresses involved, the servers that sent the email, etc.

1. General

The Message-ID header is like a digital fingerprint of a message and is usually added by the mail server that sends your message out on behalf of your mail client. The Message-ID looks a bit like a really long and cryptic email address. Here the "Message-ID" field allow you to choose how the domain part will be constructed.

The recommended way, using {SENDER_HOST} default variable, the sender email domain configured with the SMTP server will be extracted and added to the Message-ID. For exemple the sender email address is, username@gmail.com which gives :

KI1NZU8IY8U4.WJR5J57ZK90S1@gmail.com

With the {TO_HOST} variable, the recipient's domain will be extracted and added to the Message-ID. For example, the message sent is for username@company.com which gives :

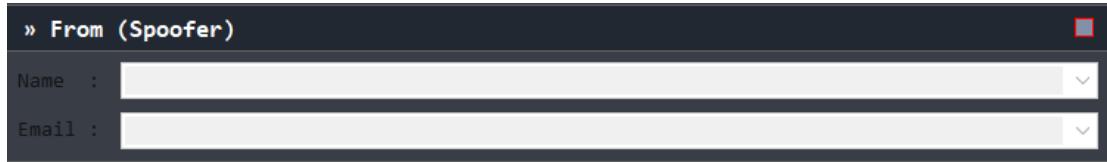

KI1NZU8IY8U4.WJR5J57ZK90S1@company.com

You can also define the same domain for all messages sent in your next email campaign by handwriting the domain directly in the input. Then you can select a "Date" if you want to overwrite the default date value. Do not forget to check the box to apply overwritting.

Overwritting date header doesn't works with public SMTP server like Google or Yahoo because they automatically change incorrect information inside the header.

2. From

The From panel allow you to spoof the “Name” and “Email” address that will appear inside the recipient mailbox. To do this please check the “Spoofed” box at the right :

Like the sender panel, “Name” field can be blank but “Email” field must be filled with a valid email address. To bypass SPF security you need to set the real sender email address configured with each SMTP server inside Servers > Settings > Sender panel. As previously specified the sender email address must be signed by SPF, DKIM and DMARC.

Spoofing does not work with free SMTP server like google or yahoo because they automatically change incorrect information in the header.

This feature will radically increase the spam score of your emails, don't hope to have a high inbox rate if you choose to use it.

3. Reply-To

The screenshot shows a dark-themed software window titled "» Reply-To". It contains two input fields: "Name :" followed by a text input field, and "Email :" followed by another text input field. Both input fields have a small downward arrow icon at their right end, likely indicating they are dropdown menus or have additional options.

When you send an email to a subscriber and they click 'Reply', the reply message is typically sent to the email address listed in the From header.

A Reply-To address is identified by inserting the Reply-To header in your email. It is the email address that the reply message is sent when you want the reply to go to an email address that is different than the From address.

In the example below, 'service@domain.com' is the Reply-To address. When a subscriber clicks 'Reply', the reply message is sent to 'service@domain.com' instead of 'marketing@domain.com'.

From : marketing@domain.com

To : exemple@domain.com

Reply-To : service@domain.com

So this feature allows you to choose a "Name" and an "Email" which will be chosen as the To header when the targeted recipient wants to reply your email. As always, the Reply-To "Name" field does not need to be filled and can stay blank, but the "Email" field must be filled with a valid email address.

This header is often used by spammers to get a response on a spoofed email, when activated it can increase the spam score of your message.

4. List-Unsubscribe

The official list-unsubscribe definition according to [RFC2369](#) is as follows :

“The list-unsubscribe field describes the command (preferably using mail) to directly unsubscribe users by removing them from the list.”

Simply put, this is an unsubscribe link or button displayed next to the email sender information. The header is an especially user-friendly place for the opt-out function because the reader doesn't have to search through the body of the email text to find it. Here is how it looks in Gmail:

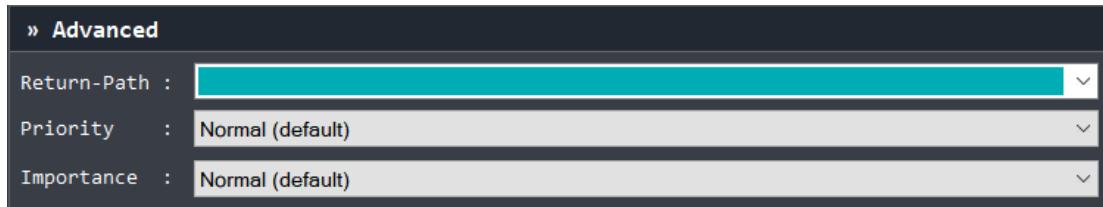

In case you are sending a newsletter campaign or any other marketing campaign, it is highly suggested to enable and configure this header correctly, it will increase the inbox rate of your emails and the trust from your recipient.

To correctly use this header you need to fill “Email” field with a valid email address, you will receive all unsubscribe requests from your recipients on this email, and the “URL” field with a valid http / https URL to redirect recipients on a website page where they can unsubscribe from your mailing list.

4 . Advanced

The “Return-Path” field can stay blank if you don't want to use it else it must be filled with a valid email address. This email address will receive all bounce back emails when sending failed, if Return-Path email is not specified all bounce back emails will be sent to sender email address.

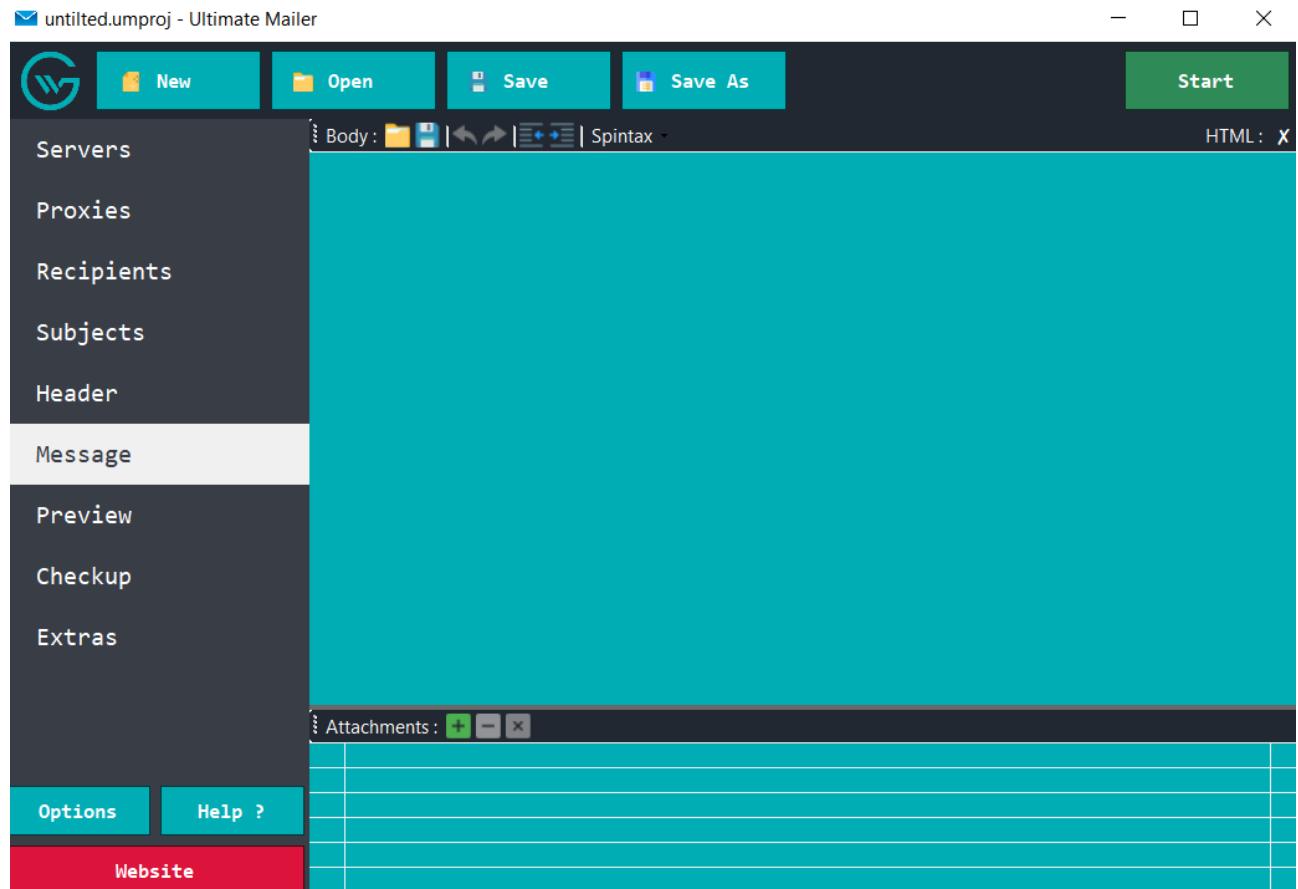

The fields "Priority" and "Importance" of the header of the message allows to modify the display in the mailbox of the recipient. This attracts the eyes of the user and can capture his attention.

VII. Message

Here you can wrote the body of your emails by using Plain Text or HTML format directly inside the software and add somes attached file to your email.

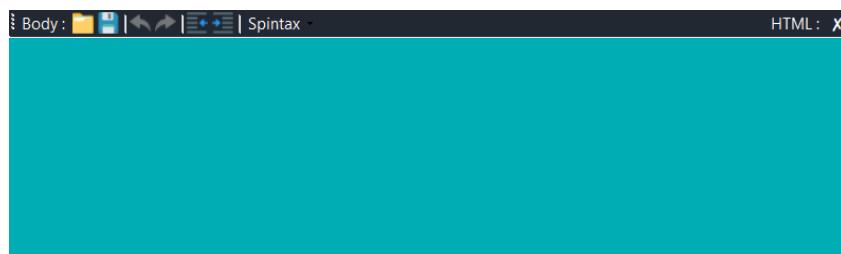

1. Body

The body of an email message is essentially the letter inside of the envelope. Consider how you read a letter you receive in the postal mail: you open the envelope and unfold the paper to view the contents of the message.

Similarly, once a recipient opens an email message, the email body section is displayed in its entirety. Separate from the header, the body is a freeform field where you insert as much text as you want, and add supporting links, images, or attachments (though attachments are usually displayed separately).

When you send an email message, you're not limited in terms of how much text you can use. However, email servers do have limits on how big a message they will accept. Common maximum sizes for email bodies, including attachments, are 10 MB to 25 MB.

By default the message body format is Plain Text, you can switch up to HTML by clicking button named “Disable” in red at the top right of the panel. The button will change his state and become “Enable” in green, that told you the body format is now in HTML.

Please note that when you used HTML format, a Plain Text alternative is automatically generate by the software, it increase inbox rate and compatibility for all mailbox providers.

2. Attachments

This section allows you to attach files to your e-mail. Click the + button and choose your file in the opened dialog box.

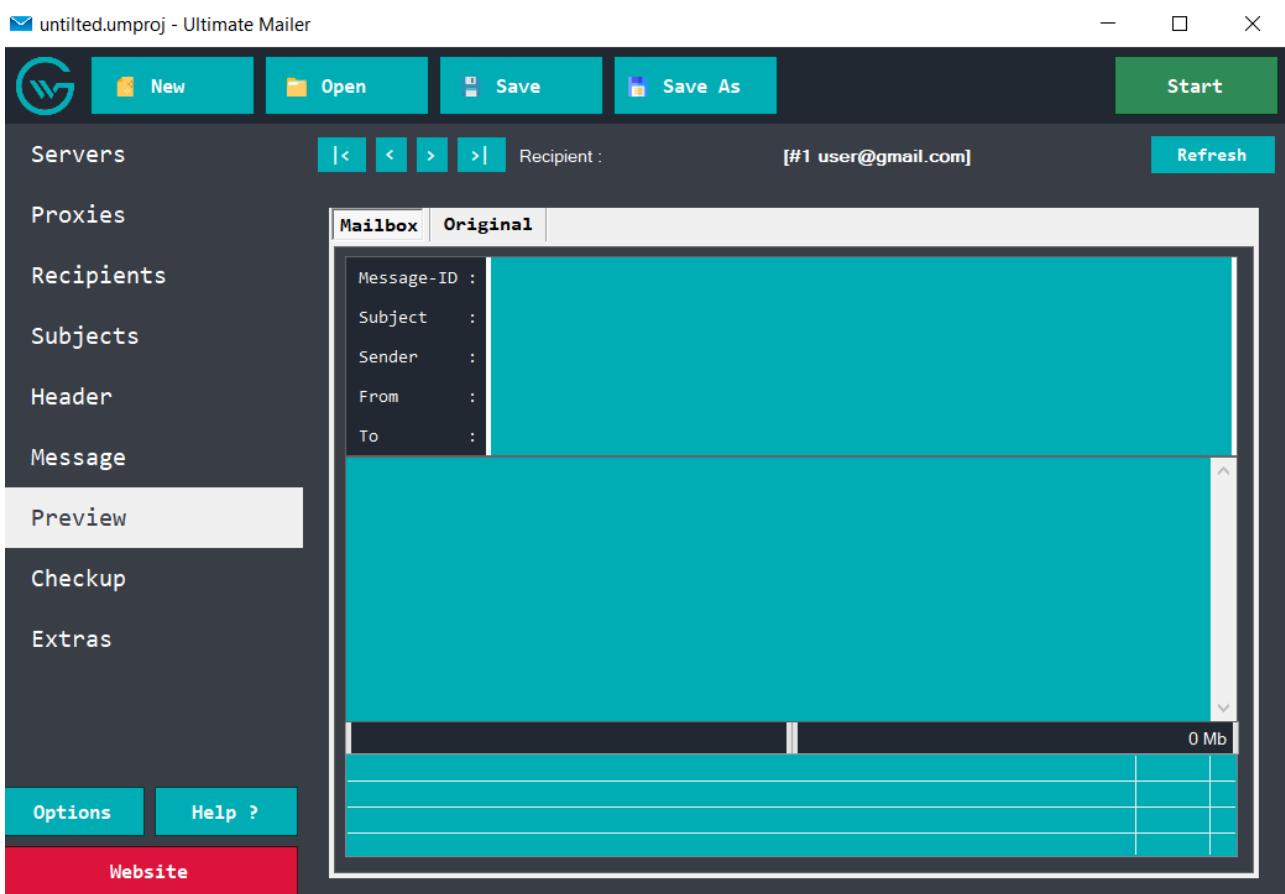

Warning most of the time, SMTP servers do not allow sending and receiving EXE attachments with emails. Therefore, they can blacklist your server if you try to send this type of file.

Pay attention to the size of attached files because most SMTP servers have limits on the size of sent and received messages. Common maximum sizes for email bodies, including attachments, are 10 MB to 25 MB.

VIII. Preview

In this tab, you can preview your message as if you were in the recipient's mailbox with the “Mailbox” tab, also preview the original message header, most of times called the raw message with the “Original” tab, and optionally go back if you find an error or want to change something.

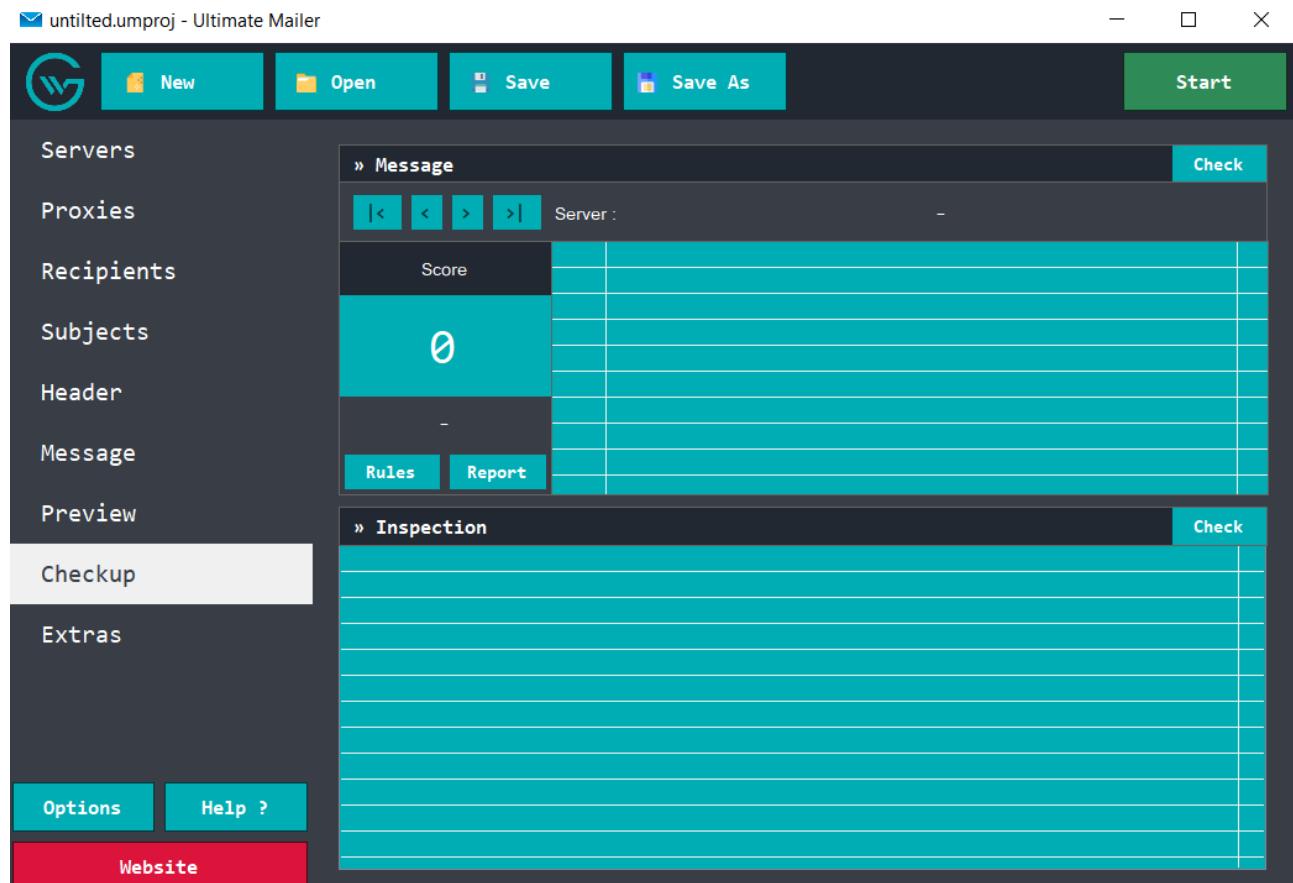

To preview your message, please select a recipient with the blue arrows then click on the “Refresh” button to update the view.

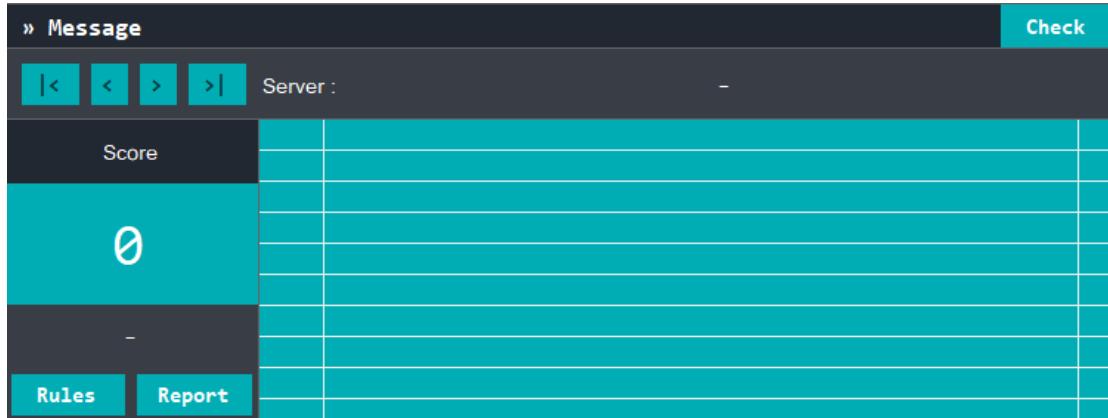

IX. Checkup

In this tab you will find all the tools to create a high quality email campaign. To keep your email sending reputation and the open rate of yours messages as high as possible.

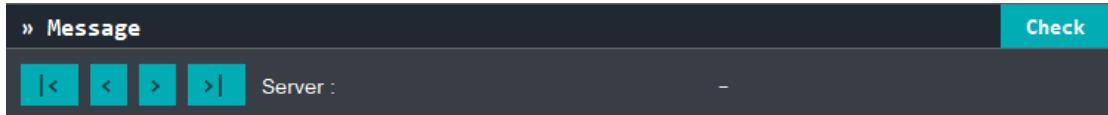

1. Message

The process is the same as [mail-tester.com](#), first your message is sent from your SMTP to a server, then it's scanned by Spamassassin and the result is returned back on the software. You should select one of your SMTP servers with the blue arrow to sendout the email.

Then by clicking "Check" button you can test the quality of your message. The lower is the score of your message, the better is its quality. You can see in the list on the right the details of this check to understand what you need to improve or keep in this message.

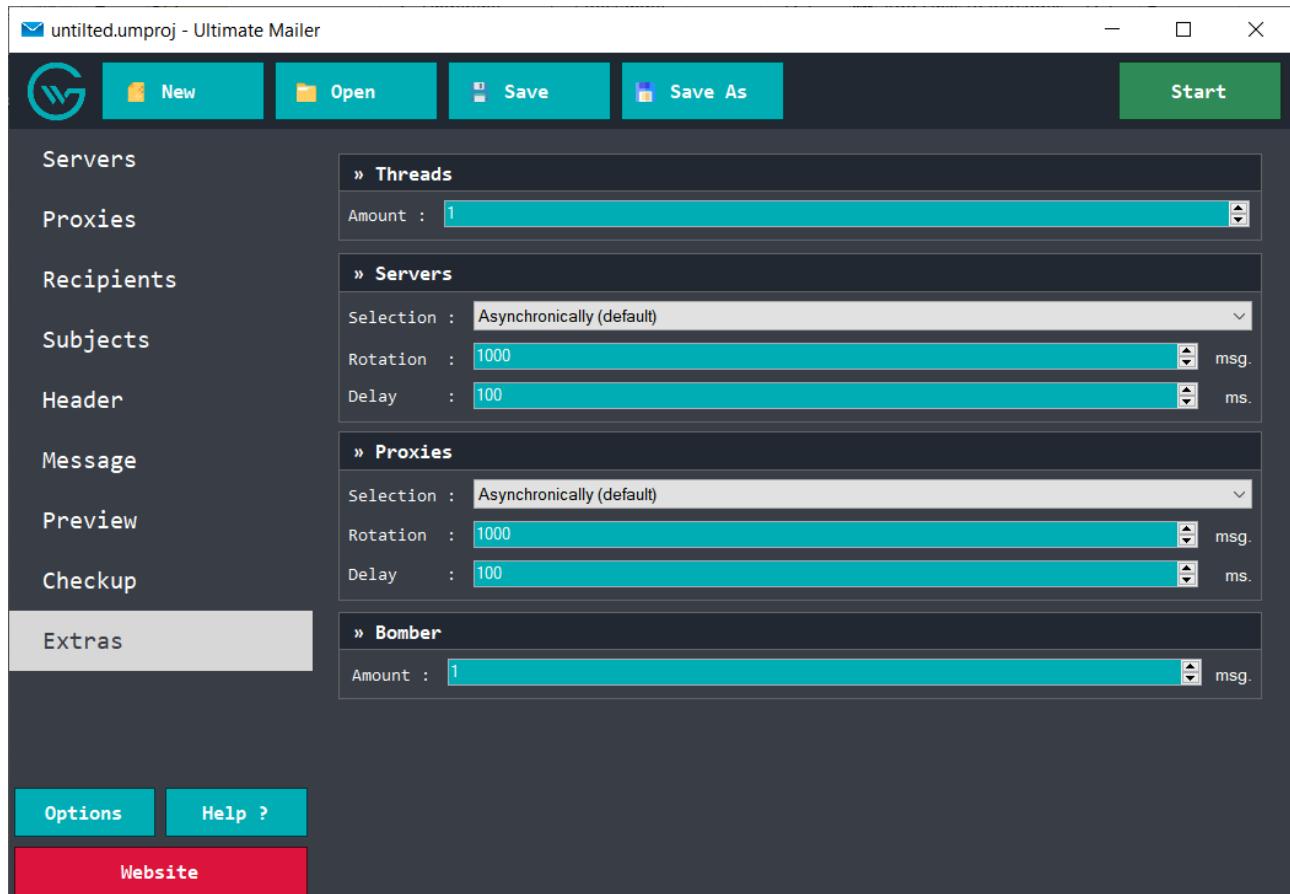

If you have a rules without any description you can click "... button, and then get the name of the empty rule in the more detailed list on the right, then you can check the description of this rule by reading spamassassin documentation. You can also copy the raw message after it has passed through your mail server by clicking the "Raw" button.

X. Extras

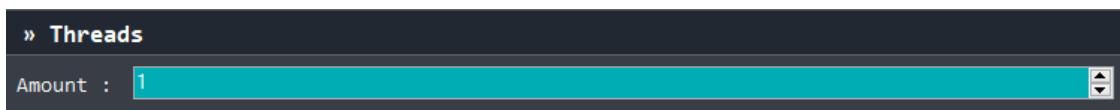

This is one of the most important tabs of the application take your time to configure it properly. It allows you to define the rules and the way of email campaign execution.

1. Threads

In computer science, a thread of execution is the smallest sequence of programmed instructions that can be managed independently by a scheduler, which is typically a part of the operating system.

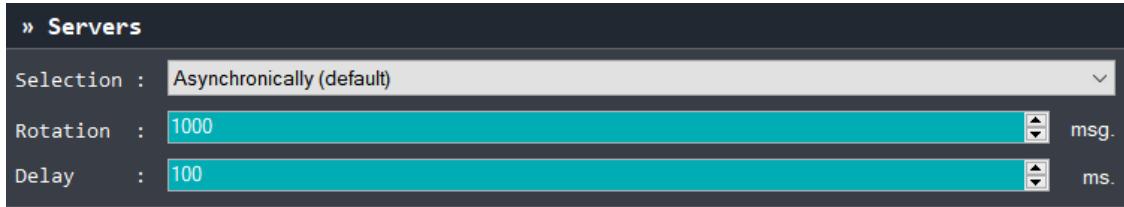

Here you can set the number of threads, between 1 and 500, each thread will run separately from each other at the same time, so your emails will be sent faster.

Don't use too many threads if your processor doesn't have enough cores, else they will be queued and executed one by one, it may also freeze the program user interface.

2. Servers

Here you can define how your mail server are selected and rotated by the software during your email campaign. First of all you need to choose a "Selection" method :

Asynchronously : It select a different SMTP server for each thread and then rotate them based on other threads. For example '#1 thread' uses '#1 server', '#2 thread' uses '#2 server', when '#1 thread' needs to rotate it's server, it will use '#3 server'.

Synchronously : This selects the SMTP server in the order they were added, threads can use the same server at the same time. For example '#1 thread' uses '# 1 server', '#2 thread' uses '#1 server', when '#1 thread' needs to rotate it's server, it will use '#2 server'.

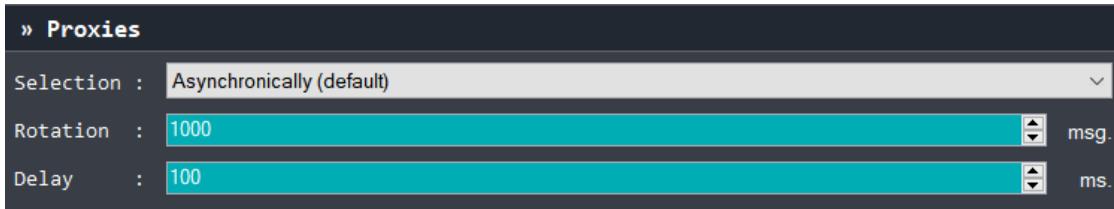

Randomly : This selects the SMTP server in a random way, threads can probably use the same server at the same time. For example '#1 thread' uses '#12 server', '#2 thread' uses '#9 server', when '#1 thread' needs to use another server, it will use '#3 server'.

The "Rotation" value define after how many emails sent a thread should use another server if there is one available. If you don't want to use the rotation feature because you have only one SMTP server just put the highest value as possible in this field.

To complete the "Delay" field defines how many milliseconds the program must wait between each server rotation.

3. Proxies

Here you can define how your proxies server are selected and rotated by the software during your email campaign. First of all you need to choose a "Selection" method :

Asynchronously : This selects a different proxy server for each SMTP and then rotate them based on other servers usage. For example '#1 server' uses '#1 proxy', '#2 server' uses '#2 proxy', when '#1 server' needs to rotate it's proxy, it will use '#3 proxy'.

Synchronously : This selects the proxies in the order they were added, servers can use the same proxy at the same time. For example '#1 server' uses '#1 proxy', '#2 server' uses '#1 proxy', when '#1 server' needs to rotate it's proxy, it will use '#2 proxy'.

Randomly : This selects the next proxy to be used in a random way, servers can probably use the same proxy at the same time. For example '#1 server' uses '#12 proxy', '#2 server' uses '#9 proxy', when '#1 server' needs to rotate it's proxy, it will use '#3 proxy'.

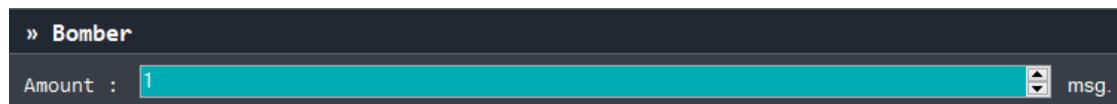

The "Rotation" value define after how many emails sent, a server should use another proxy if there is one available. If you don't want to use the rotation feature because you have only one proxy server just put the highest value as possible in this field.

To complete the "Delay" field defines how many milliseconds the program must wait between each proxy rotation.

4. Bomber

You are here to make saturated your friends mailbox ! Inside “Amount” field you can define how many times your message will be sent to each recipient. This number can be between 1 and 1M emails.

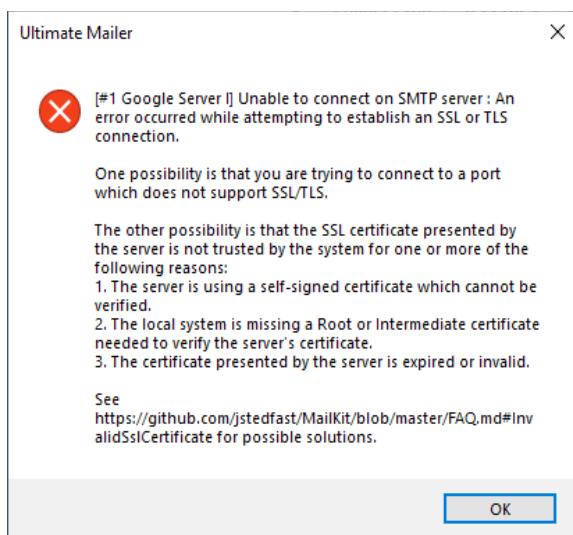

Do not to use your main email address with this feature, it can reduce your mailing reputation and therefore probably list you as a spammer on some mailbox provider.

XI. Frequently Asked Questions

1. How to solve SSL / TLS certificate error ?

Symptoms : When you try to connect on your SMTP server you got an error concerning SSL / TLS certificate.

Explanation : Ultimate Mailer always verify that the connection established between your SMTP server and the software is secure. That why you get this error message on this software and not on another one.

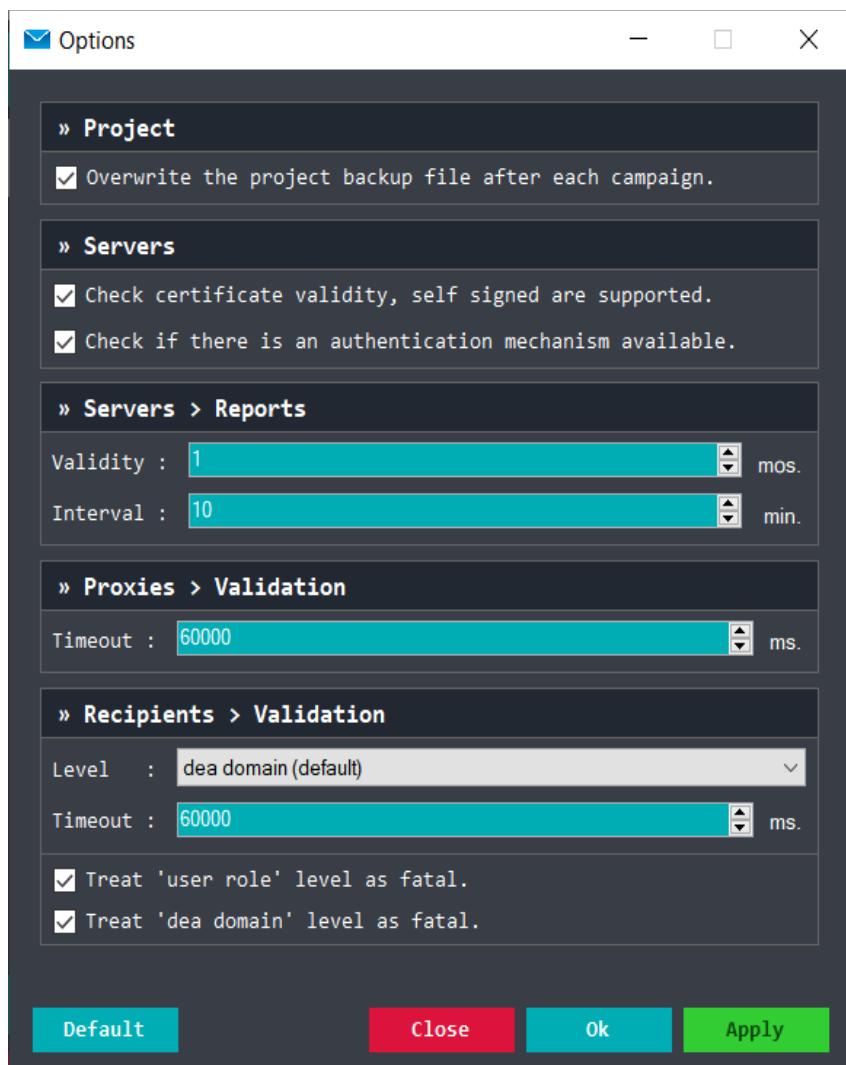

1st solution : This error can be produced by an anti-viruses like Avast, to solve it you can try to disable this settings inside your anti-viruses “Scan outbound emails (SMTP)”.

2nd solution : If the first solution don't work or you can't find this settings inside your anti-viruses. Try to completely disable both anti-viruses and firewall just to make a Test. If it works try to find the correct configurations to make this works with your anti-viruses enable and your firewall enable.

3rd solution : This solution should never be used unless if you can't solve the problem with the two first ones. So to solve this problem by a radical way disable this settings inside ultimate mailer options :

Please note that your connection to your SMTP server is no longer secure with this solution.

#1 Bulk email sending software.

2. How to make emails going to inbox ?

Rule 1. Use an SMTP server that signs your sender email address with SPF, DKIM and DMARC sender identification security.

Rule 2. Always use the email address configured with your SMTP server as sender email, never try to spoof this email address or use random email address.

Rule 3. Verify that your personal computer IP's, both IPV4 and IPV6, are not blacklisted on mxtoolbox.com.

Rule 4. Verify that the domain names linked to your SMTP servers is not blacklisted on mxtoolbox.com.

Rule 5. Avoid using one of these keywords inside your subject or message body :

- <https://www.automational.com/spam-trigger-words-to-avoid/>
- Avoid spam words that make exaggerated claims and promises.
- Avoid spam words that create unnecessary urgency and pressure.
- Avoid spam words that look like shady, spammy, or unethical behavior.
- Avoid spam words that are jargon or legalese (and everything else).

Rule 6. The email subject must be a clear and full sentence.

Rule 7. Add as many subjects as possible with some Ultimate Mailer variables / spintax.

Rule 9. Always use {SENDER_HOST} inside Message-ID header.

Rule 9. Disable From and Reply-To header inside Header tab. These are often used by spammers so mailbox providers increase spam score if one of these headers is used.

Rule 10. For newsletters and email marketing campaigns, enable the List-Unsubscribe header and add an unsubscribe button / link at the bottom of the body of your message.

Rule 11. Use some Ultimate Mailer variables / spintax inside the body of your emails.

Rule 12. Prefer using Plain Text format only for your message body. Spammer often use HTML message body to include trackers, malicious link inside the email.

Rule 13. If you choose to use HTML format, try to use the same font size and font color for the whole text, never use eye-catching colors like red and try to use the less image as possible. Also check your code to make it as clean as possible.

- Respect the HTML and CSS indentation.
- Verify your HTML and CSS syntax.
- Use a clear name for CSS class and id.
- Keep the code the most shortest as possible.
- Verify your HTML balises are open and closed properly.

Rule 14. Never use EXE file as an attachment to your message because it can be interpreted as a malicious file.

Rule 15. Always check your message inside Checkup tab before to see the spam score with each SMTP servers, keep it at the lowest as possible.

Rule 16. Always check your recipients inside Checkup tab to safe your sending reputation.
